TABLE OF CONTENTS

This document provides infectious disease information for surveillance and data entry staff. It contains a table with condition codes, condition names, and case criteria to aid in the classification and coding of conditions. It is organized alphabetically by condition name. Conditions specified as reportable in [Title 25, Texas Administrative Code, Chapter 97, Subchapter A, Control of Communicable Diseases](#) are in **bold type**. Click on a condition in the table of contents to go to the text and on the condition code to move back.

Shigellosis	60
Smallpox	61
Spotted fever group rickettsioses	62
<i>Staphylococcus aureus</i> , methicillin-or oxacillin-resistant (MRSA) - [See MRSA outbreaks only]	62
Streptococcal toxic shock syndrome (Outbreaks only)	63
<i>Streptococcus</i> , invasive group A (GAS) disease (<i>Streptococcus pyogenes</i>)	64
<i>Streptococcus</i> , invasive group B (GBS) disease (<i>Streptococcus agalactiae</i>)	64
<i>Streptococcus pneumoniae</i> , invasive disease (IPD)	64
<i>Taenia solium</i> and undifferentiated <i>Taenia</i> infection	65
Tetanus	65
Trichinellosis (Trichinosis)	65
Trichuriasis	66
Tuberculosis	67
Tularemia	69
Typhoid fever (caused by <i>Salmonella Typhi</i>)	69
Typhus, flea-borne (endemic, murine)	70
Typhus fever (epidemic louseborne, <i>R. prowazekii</i>)	71
Vancomycin-intermediate <i>Staphylococcus aureus</i> (VISA)	72
Vancomycin-resistant <i>Staphylococcus aureus</i> (VRSA)	72
Varicella (chickenpox)	73
<i>Vibrio parahaemolyticus</i>	73
<i>Vibrio vulnificus</i>	74
Vibriosis, other or unspecified	74
Viral hemorrhagic fever (VHF) Non-Ebola	75
West Nile neuroinvasive disease (WNND)	75
West Nile fever	75
Western equine encephalitis virus (WEE)	75
Yellow fever	76
Yersiniosis	76
Zika	77

DEFINITION OF TERMS

Clinically compatible case: Medical history and/or signs and symptoms generally compatible with the disease, as described in the clinical description

Confirmed case: A case that is classified as confirmed for reporting purposes

Epidemiologically linked case: A case in which a) the patient has had contact with one or more persons who either have/had the disease or have been exposed to a point source of infection (i.e., a single source of infection, such as an event leading to a foodborne-disease outbreak, to which all confirmed case-patients were exposed) and b) transmission of the agent by the usual modes of transmission is plausible

- A case can be considered epidemiologically linked to a laboratory-confirmed case if at least one case in the chain of transmission is laboratory confirmed.

Laboratory-confirmed case: A case that is confirmed by one or more of the laboratory methods listed in the case definition under Laboratory Confirmation Tests. While other laboratory methods can be used in clinical diagnosis, only those listed are accepted as laboratory confirmation for national and state reporting purposes.

Probable case: A case that is classified as probable for reporting purposes

Supportive or presumptive laboratory results: Specified laboratory results that are consistent with the diagnosis, yet do not meet the criteria for laboratory confirmation

Suspect case: A case that is classified as suspect for reporting purposes

Normally sterile site: Invasive diseases typically cause significant morbidity and mortality. Sterile sites include:

- Blood (excluding cord blood)
- Bone or bone marrow
- Cerebrospinal fluid (CSF)
- Pericardial fluid
- Peritoneal fluid
- Pleural fluid

The following are also considered sterile sites when certain other criteria are met:

- Internal body sites (brain, heart, liver, spleen, vitreous fluid, kidney, pancreas, lymph node or ovary) when the specimen is collected aseptically during a surgical procedure
- Joint fluid when the joint surface is intact (no abscess or significant break in the skin)

Although placentas and amniotic fluid from an intact amnion are not considered sterile sites, isolation of Group B streptococci or *Listeria* from these sites may qualify as invasive disease. Consult the Sterile Site and Invasive Disease Determination flowchart in Appendix A of the EAIDB Investigation Guidelines for more information:

https://www.dshs.state.tx.us/idcu/health/infection_control/Investigation-Guidance/

Normally sterile sites do not include:

- Anatomical areas of the body that normally harbor either resident or transient flora (bacteria) including mucous membranes (e.g., throat, vagina), sputum, and skin; abscesses; or localized soft tissue infection

[Table of Contents](#)

ABBREVIATIONS

Laboratory Test Abbreviations

CF – Complement fixation
CLSI- Clinical and Laboratory Standards Institute
CSF – Cerebrospinal fluid
DFA – Direct fluorescent antibody
DNA – Deoxyribonucleic acid
EEG - Electroencephalogram
EIA – Enzyme immunoassay
ELISA – Enzyme-linked immunosorbent assay
HA – Hemagglutination
HI – Hemagglutination inhibition
ID – Immunodiffusion
IFA – Indirect fluorescent antibody test
IgG – Immunoglobulin G
IgM – Immunoglobulin M
IHA – Indirect hemagglutination
IHC – Immunohistochemistry
LA – Latex agglutination
MA - Microagglutination
MIC – Minimum inhibitory concentration
MRI – Magnetic resonance imaging
NAT – Nucleic acid testing
PCR – Polymerase chain reaction
PRNT – Plaque reduction neutralization test
RIBA – Recombinant immunoblot assay
RIPA – Radio-immune precipitation assay
rRT-PCR – Real-time reverse transcriptase polymerase chain reaction
WB – Western blot

Hepatitis Test Markers

Hepatitis A – HAV
Anti-HAV – hepatitis A antibody
Anti-HAV IgM– hepatitis A IgM antibody
Hepatitis B – HBV
HBcAb or anti-HBc – hepatitis B core antibody
HBc IgM or anti-HBc IgM – hepatitis B core IgM antibody
HBsAb or anti-HBs – hepatitis B e antibody
HBsAg – hepatitis B e antigen
HBsAb or anti-HBs – hepatitis B surface antibody
HBsAg – hepatitis B surface antigen
Hepatitis C – HCV
Anti HCV – hepatitis C antibody
HCV RNA – hepatitis C nucleic acid
HCV NAT – hepatitis C nucleic acid testing
HCV RIBA – hepatitis C recombinant immunoblot assay
Hepatitis D – HDV
Anti-HDV – hepatitis D antibody
Hepatitis E – HEV
Anti-HEV IgM – hepatitis E IgM antibody

Other Abbreviations:

ALT - Alanine transaminase
ARDS - Acute Respiratory Distress Syndrome
AST –Aspartate transaminase
CDC – Centers for Disease Control and Prevention
DSHS –Department of State Health Services
EAIDB – Emerging and Acute Infectious Disease Branch
FDA – Food and Drug Administration
ILI – Influenza-Like Illness
NDM-1 - New Delhi Metallo-beta-lactamase-1
NPDPS - The National Prion Disease Pathology Surveillance Center
TAC- Texas Administrative Code
VHF – Viral hemorrhagic fever

NOTES

***Rickettsia* Classification**

The classification of *Rickettsia* into three groups (spotted fever, typhus, and scrub typhus) was based on serology. This grouping has since been confirmed by DNA sequencing except for *R. felis* which is genetically more closely related to the spotted fever group *Rickettsia*. The human pathogens are included in the following conditions. [Spotted fever group rickettsioses](#) is defined by antigenic group (spotted fever group) and vector (tick). [Murine typhus](#) contains flea-borne species of both the typhus (*Rickettsia typhi*) and spotted fever groups (*Rickettsia felis*). [Epidemic typhus](#) (*Rickettsia prowazekii*) belongs to the typhus group and is louseborne. Scrub typhus (*Orientia tsutsugamushi*, formerly classified as *Rickettsia tsutsugamushi*), a scrub typhus group species transmitted by mites, and rickettsialpox (*Rickettsia akari*), a spotted fever group species transmitted by mites, are not reportable. A table classifying Rickettsial species known to cause disease in humans by antigenic group, disease, primary vector, and reservoir occurrence can be found in the Centers for Disease Control and Prevention, *Traveler's Health Yellow Book* at <http://wwwnc.cdc.gov/travel/yellowbook/2010/chapter-5/rickettsial-and-related-infections.aspx>.

***Streptococcus* Classification**

Streptococci are facultatively anaerobic, gram-positive organisms that often occur as chains or pairs. There are four different classification systems for *Streptococcus* species, clinical (pyogenic, oral, enteric), hemolysis (alpha-hemolysis, beta-hemolysis, gamma-hemolysis), serological (Lancefield: A-H and K-U), and biochemical (physiological).

Lancefield group

Streptococci are subdivided into groups by antibodies that recognize surface antigens. The serologic reactivity of "cell wall" polysaccharide "C" antigens was described by Rebecca Lancefield. Twenty group-specific antigens were established, Lancefield A-H and K-U. Clinically significant Lancefield groups include A, B, C, F, and G. Some streptococci such as *Streptococcus pneumoniae* and the viridans streptococci are Lancefield group nontypeable.

Hemolytic reaction

The type of hemolytic reaction displayed on blood agar has also been used to classify the streptococci. Beta-hemolysis is associated with complete lysis of red cells surrounding the colony, whereas alpha-hemolysis is a partial or "green" hemolysis associated with reduction of red cell hemoglobin. Nonhemolytic colonies have been termed gamma-hemolytic.

The property of hemolysis is not very reliable for the absolute identification of streptococci, but it is widely used in rapid screens for identification.

Reportable *Streptococcus*

[Group A *Streptococcus*](#) (GAS, *Streptococcus pyogenes*) - Lancefield Group A streptococci are nearly always beta-hemolytic.

[Group B *Streptococcus*](#) (GBS, *Streptococcus agalactiae*) - Lancefield Group B streptococci are usually beta-hemolytic, but can also be alpha or gamma hemolytic.

[Streptococcus pneumoniae](#) (pneumococcus) - Most strains of *S. pneumoniae* are alpha-hemolytic but can cause β -hemolysis during anaerobic incubation. They are nontypeable by Lancefield group.

[Table of Contents](#)

CASE CRITERIA

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Acute Flaccid Myelitis 11120	<p>An illness with onset of acute focal limb weakness. Multiple etiologic agents may cause acute flaccid myelitis.</p> <p><i>Confirmed:</i> An illness with onset of acute focal limb weakness AND laboratory confirmation.</p> <p><i>Probable:</i></p> <ul style="list-style-type: none"> An illness with onset of acute focal limb weakness AND Cerebrospinal fluid (CSF) with pleocytosis (white blood cell count >5 cells/mm³, may adjust for presence of red blood cells by subtracting 1 white blood cell for every 500 red blood cells present). 	<ul style="list-style-type: none"> A magnetic resonance image (MRI) showing spinal cord lesion largely restricted to gray matter* and spanning one or more spinal segments A specific pathogen is not needed to confirm the diagnosis. <p>*Terms in the spinal cord MRI report such as “affecting mostly gray matter,” “affecting the anterior horn or anterior horn cells,” “affecting the central cord,” “anterior myelitis,” or “poliomyelitis” would all be consistent with this terminology. If still unsure if this criterion is met, consider consulting the neurologist or radiologist directly.</p>
Amebiasis 11040	<p>Infection of the large intestine by <i>Entamoeba histolytica</i> can vary in severity, ranging from an asymptomatic infection to mild, chronic diarrhea to fulminant dysentery. Extraintestinal infection can occur (e.g., hepatic abscess).</p> <p><i>Confirmed, intestinal amebiasis:</i> A clinically compatible illness that is laboratory confirmed</p> <p><i>Suspect, intestinal amebiasis:</i> A clinically compatible case with <i>E. histolytica</i> detected in stool by use of an antigen-based fecal immunoassay</p> <p><i>Confirmed, extra-intestinal amebiasis:</i></p> <ul style="list-style-type: none"> A case with demonstration of the organism, <i>E. histolytica</i>, in at least one extra-intestinal tissue sample, OR A symptomatic person (with clinical or radiographic findings consistent with extra-intestinal infection) and demonstration of specific antibody against <i>E. histolytica</i> as measured by reliable immunodiagnostic test (e.g., EIA) and PCR based assays 	<p>Intestinal amebiasis</p> <ul style="list-style-type: none"> Demonstration of cysts or trophozoites of <i>E. histolytica</i> in stool, <p>OR</p> <ul style="list-style-type: none"> Demonstration of trophozoites in tissue biopsy or ulcer scrapings by culture or histopathology <p>Extra-intestinal amebiasis</p> <ul style="list-style-type: none"> Demonstration of <i>E. histolytica</i> trophozoites in extraintestinal tissue

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
<p>Amebic meningitis/encephalitis, other 10096</p>	<p>There are three amebae other than <i>Naegleria fowleri</i> that are known to cause human amebic central nervous system (CNS) infections: <i>Balamuthia mandrillaris</i>, <i>Acanthamoeba</i> species, and <i>Sappinia</i> species. <i>Acanthamoeba</i> species, <i>Balamuthia mandrillaris</i>, and <i>Sappinia</i> species are opportunistic free-living amebae that might invade the brain through the blood, probably from a primary infection in the skin (from ulcers or dermatitis) or sinuses. Amebic CNS infection may also occur through organ transplantation. Once in the brain, <i>Acanthamoeba</i> species cause granulomatous amebic encephalitis (GAE), <i>Balamuthia</i> causes meningoencephalitis and/or GAE, and <i>Sappinia</i> species cause amebic encephalitis. The incubation period for <i>Balamuthia</i> is not well-characterized but has been observed to range from two weeks to months or possibly years. GAE caused by <i>Acanthamoeba</i> and <i>Balamuthia</i> often has a slow and insidious onset and develops into a subacute or chronic disease lasting several weeks to months; however, <i>B. mandrillaris</i> infections associated with organ transplantation have an especially rapid clinical course. Although immunosuppressed persons (e.g., HIV/AIDS, organ transplantation) are likely at greater risk of amebic CNS infection, these infections can also occur in immunocompetent persons.</p> <p>Initial symptoms of amebic CNS infection might include headache, photophobia, and stiff neck accompanied by positive Kernig's and Brudzinski's signs. Other symptoms might include nausea, vomiting, low-grade fever, muscle aches, weight loss, mental-state abnormalities, lethargy, dizziness, loss of balance, cranial nerve palsies, other visual disturbances, hemiparesis, seizures, and coma. For <i>Balamuthia</i> infections, painless skin lesions appearing as plaques a few millimeters thick and one to several centimeters wide have been observed in some patients (especially patients outside the U.S.), preceding the onset of neurologic symptoms by one month to approximately two years. Once <i>Acanthamoeba</i> or <i>Balamuthia</i> disease progresses to neurologic infection, it is generally fatal within weeks or months; however, a few patients have survived this infection. Only one case of amebic encephalitis from <i>Sappinia</i> infection has been reported worldwide, and the patient survived.</p> <p>Confirmed: A clinically compatible case that is laboratory confirmed</p> <p>See also Amebic meningoencephalitis, primary (PAM)</p>	<p>In CSF, biopsy, or tissue specimens, detection of free-living amebic organisms (other than <i>Naegleria fowleri</i>) by:</p> <ul style="list-style-type: none"> ▪ Microscopic examination, OR ▪ Detection of nucleic acid (e.g., PCR), OR ▪ Detection of antigen (e.g., DFA) <p>Contact DSHS epidemiologist for meningitis (amebic) at 800-252-8239 if suspected. DSHS will assist in coordinating specimen and/or electronic images submission to the CDC for verification. Collection & shipping procedures can be found at: http://www.cdc.gov/parasites/acanthamoeba/ and http://www.cdc.gov/parasites/balamuthia/</p> <p>Comments: <i>Acanthamoeba</i> and <i>B. mandrillaris</i> can cause clinically similar illnesses and might be difficult to differentiate using commonly available laboratory procedures. Definitive diagnosis by a reference laboratory might be required. A negative test on CSF does not rule out <i>Acanthamoeba</i> or <i>Balamuthia</i> infection because these organisms are not commonly present in the CSF.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Amebic meningoencephalitis, primary (PAM) 80750	<p><i>Naegleria fowleri</i> is a free-living ameboflagellate that invades the brain and meninges via the nasal mucosa and olfactory nerve to cause acute, fulminant hemorrhagic meningoencephalitis (primary amebic meningoencephalitis – PAM), primarily in healthy children and young adults with a recent history of exposure to warm fresh water. Initial signs and symptoms of PAM begin one to 14 days after infection and include sudden onset of headache, fever, nausea, vomiting, and stiff neck accompanied by positive Kernig’s and Brudzinski’s signs. In some cases, abnormalities in taste or smell, nasal obstruction and nasal discharge might be seen. Other symptoms might include photophobia, mental-state abnormalities, lethargy, dizziness, loss of balance, other visual disturbances, hallucinations, delirium, seizures, and coma. After the onset of symptoms, the disease progresses rapidly and usually results in death within three to seven days. Although a variety of treatments have been shown to be active against amebae in vitro and have been used to treat infected persons, most infections have still been fatal.</p> <p>Confirmed: A clinically compatible case that is laboratory confirmed See also Amebic meningitis/encephalitis, other</p>	<p>Confirmed presence of <i>Naegleria fowleri</i> in CSF, biopsy, or tissue specimens via:</p> <ul style="list-style-type: none"> ▪ Microscopic examination, <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of nucleic acid (e.g., PCR), <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of antigen (e.g., DFA) <p>Note: When available, molecular characterization [e.g., genotype] should be reported.</p> <p>Contact DSHS epidemiologist for amebic meningitis at 800-252-8239 if suspected. DSHS will assist in coordinating specimen and/or electronic images submission to the CDC for verification. Collection & shipping procedures can be found at: http://www.cdc.gov/parasites/naegleria/diagnosis-hcp.html</p>
<i>Anaplasma phagocytophilum</i> 11090	<p>A tick-borne illness characterized by acute onset of fever and one or more of the following signs or symptoms: headache, myalgia, malaise, anemia, leukopenia, thrombocytopenia, or elevated hepatic transaminases. Nausea, vomiting, or rash can be present in some cases.</p> <p>Confirmed: A clinically compatible illness that is laboratory confirmed</p> <p>Probable: A clinically compatible illness with serological evidence of IgG or IgM antibody reactive ($\geq 1:128$) with <i>A. phagocytophilum</i> antigen by IFA, ELISA, or dot-ELISA or identification of morulae in the cytoplasm of neutrophils or eosinophils by microscopic examination</p> <p>Suspect: A case with laboratory evidence of past/present infection with <i>A. phagocytophilum</i> (e.g., laboratory report) but no available clinical information</p>	<ul style="list-style-type: none"> ▪ Demonstration of a four-fold change in IgG-specific antibody titer to <i>A. phagocytophilum</i> antigen by indirect immunofluorescence assay (IFA) in paired serum samples (one taken in first week of illness and a second taken 2-4 weeks later), <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of <i>A. phagocytophilum</i> DNA in a clinical specimen by PCR, <p>OR</p> <ul style="list-style-type: none"> ▪ Demonstration of anaplasma antigen in a biopsy/autopsy sample by IHC, <p>OR</p> <ul style="list-style-type: none"> ▪ Isolation of <i>A. phagocytophilum</i> from a clinical specimen in cell culture

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Anthrax 10350	<p>An illness with acute onset characterized by several distinct clinical forms, including the following:</p> <p><i>Cutaneous:</i> A skin lesion evolving during a period of 2-6 days from a papule, through a vesicular stage, to a depressed black eschar. Fever, malaise, and lymphadenopathy can accompany the lesion.</p> <p><i>Inhalation:</i> A prodrome resembling a viral respiratory illness, followed by hypoxia and dyspnea, or acute respiratory distress syndrome (ARDS) with resulting cyanosis and shock. Radiographic evidence of mediastinal widening or pleural effusion is common.</p> <p><i>GastroIntestinal:</i> Severe abdominal pain and tenderness, nausea, vomiting, hematemesis, bloody diarrhea, anorexia, fever and septicemia.</p> <p><i>Oropharyngeal:</i> Mucosal lesion in the oral cavity or oropharynx, with cervical adenopathy, edema, pharyngitis, fever, and possible septicemia.</p> <p><i>Meningeal:</i> Fever, convulsions, coma or meningeal signs. This syndrome is usually secondary to the above syndromes.</p> <p>Confirmed: A clinically compatible case that is laboratory confirmed</p> <p>Probable: A clinically compatible illness that does not meet the confirmed case definition, but does meet one of the following criteria:</p> <ul style="list-style-type: none"> ▪ Epidemiologic-link to a documented anthrax environmental exposure, OR ▪ Evidence of <i>B. anthracis</i> DNA, OR ▪ Positive result on serum specimen tests using the Quick ELISA Anthrax-PA kit, OR ▪ Detection of Lethal Factor (LF) in clinical serum specimens by LF mass spectrometry, OR ▪ Positive result on testing of culture from clinical specimens with the RedLine Alert test 	<ul style="list-style-type: none"> ▪ Culture and identification of <i>Bacillus anthracis</i> from clinical specimens by the Laboratory Response Network, OR ▪ Detection of <i>B. anthracis</i> antigens in tissues by IHC using both <i>B. anthracis</i> cell wall and capsule monoclonal antibodies, OR ▪ Evidence of a four-fold rise in antibodies or antigen between acute and convalescent sera using CDC IgG ELISA testing, OR ▪ Documented anthrax environmental exposure AND evidence of <i>B. anthracis</i> DNA <p>Note: As required by TAC, all <i>B. anthracis</i> isolates must be submitted to the DSHS laboratory.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
<p>Arbovirus, neuroinvasive (encephalitis/meningitis) and non-neuroinvasive</p> <p>Neuroinvasive Disease</p> <p>10073 Chikungunya 10058 Encephalitis, Cache Valley 10054 Encephalitis/Meningitis, California* 10053 Encephalitis, Eastern equine (EEE) 10078 Encephalitis, Jamestown Canyon 10059 Encephalitis, Japanese 10081 Encephalitis, La Crosse 10057 Encephalitis, Powassan 10051 Encephalitis, St. Louis (SLE) 10055 Encephalitis, Venezuelan equine (VEE) 10056 Encephalitis, West Nile (WNNd) 10052 Encephalitis, Western equine (WEE)</p> <p>Non-neuroinvasive Disease</p> <p>10072 Arbovirus, other 10066 Cache Valley Virus 10061 California serogroup virus* 11702 Chikungunya 10062 Eastern equine encephalitis virus 10075 Flavivirus, unspecified 10079 Jamestown Canyon 10068 Japanese Encephalitis virus 10082 La Crosse virus 10063 Powassan virus 10064 St. Louis encephalitis virus 10067 Venezuelan equine encephalitis Virus 10049 West Nile Fever 10065 Western equine encephalitis virus</p>	<p>For the purposes of surveillance and reporting, based on their clinical presentation, arboviral disease cases are often categorized into two primary groups: neuroinvasive disease and non-neuroinvasive disease.</p> <p>Many arboviruses cause neuroinvasive disease such as aseptic meningitis, encephalitis, or acute flaccid paralysis (AFP). These illnesses are usually characterized by the acute onset of fever with stiff neck, altered mental status, seizures, limb weakness, cerebrospinal fluid (CSF) pleocytosis, or abnormal neuroimaging. AFP may result from anterior myelitis, peripheral neuritis or post-infectious peripheral demyelinating neuropathy. Less common neurological manifestations, such as cranial nerve palsies, also occur.</p> <p>Most arboviruses are capable of causing an acute systemic febrile illness (e.g., West Nile fever) that may include headache, myalgias, arthralgias, rash, or gastrointestinal symptoms. Some viruses also can cause more characteristic clinical manifestations, such as severe polyarthralgia or arthritis due to Chikungunya virus or other alphaviruses.</p> <p>Clinical evidence of neuroinvasive disease:</p> <ul style="list-style-type: none"> ▪ Meningitis, encephalitis, acute flaccid paralysis, or other acute signs of central or peripheral neurologic dysfunction, as documented by a physician, AND ▪ Absence of a more likely clinical explanation <p>Clinical evidence of non-neuroinvasive disease:</p> <ul style="list-style-type: none"> ▪ Fever or chills as reported by the patient or a health-care provider, AND ▪ Absence of neuroinvasive disease, AND ▪ Absence of a more likely clinical explanation. <p>Neuroinvasive: Confirmed: A clinically compatible case (meets neuroinvasive clinical evidence criteria) with laboratory confirmation</p> <p>Probable: A clinically compatible case (meets neuroinvasive clinical evidence criteria) with virus-specific IgM antibodies in CSF or serum but no other testing OR with lower levels of neutralizing antibodies for another flavivirus</p> <p>Non-neuroinvasive: Confirmed: A clinically compatible case (meets non-neuroinvasive clinical evidence criteria) with laboratory confirmation</p> <p>Probable: : A clinically compatible case (meets non-neuroinvasive clinical evidence criteria) with virus-specific IgM antibodies in serum but no other testing OR with lower levels of neutralizing antibodies for another flavivirus</p>	<p>Neuroinvasive</p> <ul style="list-style-type: none"> ▪ Isolation of virus from, or demonstration of specific viral antigen or nucleic acid in, tissue, blood, CSF, or other body fluid, OR ▪ Four-fold or greater change in virus-specific quantitative antibody titers in paired sera, OR ▪ Virus-specific IgM antibodies in serum with confirmatory virus-specific neutralizing antibodies in the same or a later specimen, and a negative result for other neutralizing antibodies for arboviruses endemic to the region where exposure occurred, OR ▪ Virus-specific IgM antibodies in CSF and a negative result for other IgM antibodies in CSF for arboviruses endemic to the region where exposure occurred <p>Non-neuroinvasive</p> <ul style="list-style-type: none"> ▪ Isolation of virus from, or demonstration of specific viral antigen or nucleic acid in, tissue, blood, or other body fluid, excluding CSF, OR ▪ Four-fold or greater change in virus-specific quantitative antibody titers in paired sera, OR ▪ Virus-specific IgM antibodies in serum with confirmatory virus-specific neutralizing antibodies in the same or a later specimen and a negative result for other neutralizing antibodies for arboviruses endemic to the region where exposure occurred <p><small>*Note: California encephalitis/meningitis refers to all California serogroup viruses. California serogroup includes California encephalitis, Keystone, snowshoe hare, and trivittatus viruses. All cases of Jamestown Canyon and La Crosse should be reported separately.</small></p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Ascariasis 80770	<p>Ascariasis is a soil-transmitted helminth. Infection is generally associated with few or no overt clinical symptoms. Live worms, passed in stools or occasionally from the mouth, anus, or nose, are often the first recognized sign of infection. Larval migration may result in pulmonary manifestations such as wheezing, cough, fever, eosinophilia and pulmonary infiltration in some patients. Mild infections may result in minor abdominal discomfort, dyspepsia, and loss of appetite. Major infections may result in severe abdominal pain, fatigue, vomiting, or weight loss. In children, these symptoms can result in nutrient deficiencies resulting in growth retardation and/or cognitive impairment. Serious complications are rare but can be fatal and include intestinal obstruction by a bolus of worms, or obstruction of bile duct, pancreatic duct or appendix by one or more adult worms.</p> <p>Confirmed: A case that is laboratory confirmed</p> <p>Probable: A clinically compatible case with evidence of infection such as</p> <ul style="list-style-type: none"> ▪ An ultrasound showing worms in the pancreas or liver ▪ CT scans or MRI showing worms present in the ducts of the liver or pancreas. 	<ul style="list-style-type: none"> ▪ Microscopic identification of <i>Ascaris</i> eggs in feces, OR ▪ Microscopic identification of ascarid larvae in sputum or gastric washings, OR ▪ Identification of adult worms passed from the anus, mouth or nose

Campylobacteriosis 11020	<p>An illness of variable severity commonly manifested by diarrhea, abdominal pain, nausea and sometimes vomiting. The organism may also rarely cause extra-intestinal infections such as bacteremia, meningitis or other focal infections.</p> <p>Confirmed: A case that is laboratory confirmed</p> <p>Probable:</p> <ul style="list-style-type: none"> A case with <i>Campylobacter</i> spp. detected. in a clinical specimen using a culture independent diagnostic test (CIDT) <p>OR</p> <ul style="list-style-type: none"> A clinically compatible case that is epidemiologically linked to a case that meets the probable or confirmed laboratory criteria for diagnosis <p>Note: The use of CIDTs as stand-alone tests for the direct detection of <i>Campylobacter</i> in stool is increasing. Data regarding their performance indicate variability in the sensitivity, specificity, and positive predictive value of these assays depending on the manufacturer (CDC unpublished data). It is therefore useful to collect information on the laboratory conducting the testing using the laboratory's unique CLIA number, and when possible, type and manufacturer of the CIDT used to diagnose each case. Culture confirmation of CIDT-positive specimens is ideal, but not practical to achieve in most jurisdictions.</p>	<ul style="list-style-type: none"> Isolation of <i>Campylobacter</i> spp. in a clinical specimen
Carbapenem-resistant <i>Enterobacteriaceae</i> (CRE) 77924	<p>Carbapenem-resistant <i>Enterobacteriaceae</i> (CRE): Carbapenemase producing <i>Enterobacteriaceae</i> or carbapenem-resistant <i>Enterobacteriaceae</i>, specifically <i>Klebsiella</i> species and <i>Escherichia coli</i>, are gram-negative bacilli that have the ability to break down the carbapenem antibiotic rendering it ineffective. Carbapenem resistance by <i>Enterobacteriaceae</i> can occur by many different mechanisms, which can be transmitted from one <i>Enterobacteriaceae</i> to another. CRE can also have additional resistance mechanisms that enable them to be non-susceptible to many other classes of commonly used antibiotics.</p> <p>CRE can cause infections in almost any part of the body including bloodstream infections, ventilator- associated pneumonia, and intra-abdominal abscesses.</p> <p>Confirmed: A <i>Klebsiella</i> species or <i>E.coli</i> from any body site/ source that is laboratory confirmed.</p> <p>Additional information on CRE can be found at: http://www.cdc.gov/HAI/organisms/cre/index.html</p>	<p>CRE confirmed</p> <ul style="list-style-type: none"> <i>Klebsiella</i> species and <i>E. coli</i> that are resistant to any carbapenem, including meropenem, imipenem, doripenem, or ertapenem, <p>OR</p> <ul style="list-style-type: none"> Production of a carbapenemase (i.e. KPC, NDM, VIM, IMP, OXA-48) demonstrated by a recognized test (i.e. polymerase chain reaction, metallo-β-lactamase test, modified Hodge test, Carba NP). <p>Note: There is no requirement to submit isolates to the DSHS lab. Please contact a DSHS HAI Epidemiologist or the DSHS lab for additional information on available lab support.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Chagas disease, acute 12041	<p>Chagas disease is a parasitic infection caused by <i>Trypanosoma cruzi</i>. The acute phase is characterized by the first 8 weeks of infection, detectable parasitemia, and asymptomatic (most common) or symptomatic manifestations of disease which can include any of the following:</p> <ul style="list-style-type: none"> ▪ Fever, malaise, rash, body aches, headache, loss of appetite, vomiting, diarrhea, hepatomegaly, splenomegaly, lymphadenopathy, Chagoma (nodular swelling at site of inoculation), Romaña's sign (unilateral swelling of the eyelid) and rarely, acute myocarditis and/or meningoencephalitis. <p>Confirmed: A case (asymptomatic or symptomatic) that has confirmatory laboratory testing</p> <p>Probable: A clinically compatible case with supportive laboratory testing* and documented exposure** within 8 weeks of illness onset or diagnosis</p> <p>*Supportive laboratory testing includes:</p> <ul style="list-style-type: none"> ▪ Positive diagnostic serology for <i>T. cruzi</i> antibodies <p>OR</p> <ul style="list-style-type: none"> ▪ Positive blood donor screening test PLUS a positive supplemental test <p>**Documented exposure may include history of travel to an endemic country</p>	<ul style="list-style-type: none"> ▪ Identification of <i>T. cruzi</i> by microscopy including: <ul style="list-style-type: none"> ▪ Microscopic examination of <i>T. cruzi</i> by: <ul style="list-style-type: none"> ▪ Wet mount – motile trypanosomes OR ▪ Thick & thin smears - Giemsa stain <p>OR</p> <ul style="list-style-type: none"> ▪ Isolation of the agent by <ul style="list-style-type: none"> ▪ Culture (specialized media - NNN, LIT) OR ▪ Inoculation into mice, OR ▪ Xenodiagnosis <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of <i>T. cruzi</i> DNA by polymerase chain reaction (PCR) <p>Note: There is no gold standard for screening or diagnosis. No single supportive test has the sensitivity and specificity to be relied on alone.</p> <p>Congenital infections are considered acute up to 8 weeks of age and can be diagnosed by confirmatory tests. Infants < 9 months & epidemiologically-linked need to be retested after 9 months of age.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Chagas disease, chronic indeterminate 12043	<p>Following the acute phase, most infected people enter into a prolonged, asymptomatic form of disease (called “chronic indeterminate”) during which few or no parasites are found in the blood. During this time, most people are unaware of their infection. Many people remain asymptomatic for life and never develop chronic Chagas-related symptoms.</p> <p>Confirmed: An asymptomatic case >9 months of age with confirmatory lab results obtained more than 8 weeks after documented exposure**</p> <p>Probable: An asymptomatic case >9 months of age with supportive laboratory testing* obtained more than 8 weeks after documented exposure</p> <p>*Supportive laboratory testing includes:</p> <ul style="list-style-type: none"> ▪ Positive diagnostic serology for <i>T. cruzi</i> antibodies OR ▪ Positive blood donor screening test PLUS a positive supplemental test <p>Note: Women with chronic indeterminate disease can transmit infection to their unborn babies. Infants <9 months of age with a mother from an endemic area, in absence of direct detection of the organism, cannot be classified or ruled out due to maternal antibodies; perform serology at 9 months of age and classify based on presence or absence of symptoms as chronic symptomatic or chronic indeterminate case definition.</p> <p>**Documented exposure may include history of travel to an endemic country</p>	<ul style="list-style-type: none"> ▪ Detection of antibody specific to <i>T. cruzi</i> by TWO distinct diagnostic tests*** <p>***Tests must be performed at Centers for Disease Control and Prevention (CDC)</p> <p>Note: No single supportive test has the sensitivity and specificity to be relied on alone, thus two different methods or antibodies specific to <i>T. cruzi</i> are used.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Chagas disease, chronic symptomatic 12042	<p>Much like the chronic indeterminate phase, the chronic symptomatic phase of disease (more than 8 weeks post infection) is characterized by undetectable parasitemia. However, an estimated 20 - 30% of infected people will develop debilitating and sometimes life-threatening medical problems over the course of their lives. Complications of chronic Chagas disease may include: heart rhythm abnormalities that can cause sudden death, a dilated heart that doesn't pump blood well and/or a dilated esophagus or colon, leading to difficulties with eating or passing stool.</p> <p>Confirmed: A physician- diagnosed case of chronic Chagas disease in a patient > 9 months of age with confirmatory laboratory results obtained more than 8 weeks after documented exposure** or symptom onset</p> <p>Probable: A physician diagnosed case of chronic Chagas disease > 9 months of age with supportive laboratory results* obtained more than 8 weeks after a documented exposure** or symptom onset</p> <p>* Supportive laboratory testing includes:</p> <ul style="list-style-type: none"> ▪ Positive diagnostic serology for <i>T. cruzi</i> antibodies OR ▪ Positive blood donor screening test PLUS a positive supplemental test <p>**Documented exposure may include history of travel to an endemic country</p>	<ul style="list-style-type: none"> ▪ Detection of antibody specific to <i>T. cruzi</i> by TWO distinct diagnostic tests*** <p>***Tests must be performed at Centers for Disease Control and Prevention (CDC)</p> <p>Note: No single supportive test has the sensitivity and specificity to be relied on alone, thus two different methods or antibodies specific to <i>T. cruzi</i> are used.</p>

Cryptosporidiosis 11580	<p>A gastrointestinal illness characterized by diarrhea and one or more of the following: diarrhea duration of 72 hours or more, abdominal cramping, vomiting, or anorexia.</p> <p>Confirmed: A case that is laboratory confirmed</p> <p>Probable:</p> <ul style="list-style-type: none"> ▪ A case with <i>Cryptosporidium</i> antigen detected by a screening test method such as, the immunochromatographic card/rapid card test or a laboratory test of unknown method <p>OR</p> <ul style="list-style-type: none"> ▪ A clinically compatible case that is epidemiologically linked to a confirmed case by one of the following means: <ul style="list-style-type: none"> ▪ Household or other close contact to a lab-confirmed case with onset of symptoms within 1 month (before or after), OR ▪ Exposure to an outbreak at a body of water or water facility involving at least 2 lab-confirmed cases and onset of symptoms within one month (before or after) of one or more of these cases 	<ul style="list-style-type: none"> ▪ Detection of <i>Cryptosporidium</i> organisms or DNA in stool, intestinal fluid, tissue samples, biopsy specimens, or other biological sample by certain laboratory methods with a high positive predictive value (PPV), e.g., DFA, PCR, EIA, or light microscopy of stained specimen
Cyclosporiasis 11575	<p>An illness of variable severity caused by the protozoan parasite <i>Cyclospora cayetanensis</i>. The most common symptom is watery diarrhea. Other common symptoms include loss of appetite, weight loss, abdominal cramps/bloating, nausea, body aches, and fatigue. Vomiting and low grade fever also may be noted. Relapses and asymptomatic infections can occur.</p> <p>Confirmed: A laboratory-confirmed case with or without clinical symptoms</p> <p>Probable: A clinically compatible case that is epidemiologically linked to a confirmed case</p>	<ul style="list-style-type: none"> ▪ Detection—in symptomatic or asymptomatic persons— of <i>Cyclospora</i>: <ul style="list-style-type: none"> ▪ Oocysts in stool by microscopic examination, or in intestinal fluid/aspirate or intestinal biopsy specimens, <p>OR</p> <ul style="list-style-type: none"> ▪ Demonstration of sporulation, or DNA (by PCR) in stool, intestinal fluid/aspirate or intestinal biopsy specimens

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
<p>Cysticercosis (also see <i>Taenia solium</i>) 12031</p>	<p>Cysticercosis is an infection (tissue) caused by the larval form of the pork tapeworm, <i>Taenia solium</i>. Infection occurs when the tapeworm eggs are ingested, hatch into larvae, and migrate to tissues where they form cysticerci (cysts). The symptoms of cysticercosis reflect the development of cysticerci in various sites. Subcutaneous cysticerci may be visible or palpable.</p> <p>When cysticerci are found in the brain, the condition is called neurocysticercosis, which can cause diverse manifestations including seizures, mental disturbances, focal neurologic deficits, and signs of space-occupying intracerebral lesions. Death can occur suddenly. Extracerebral cysticercosis can cause ocular, cardiac, or spinal lesions with associated symptoms. Asymptomatic subcutaneous nodules and calcified intramuscular nodules can be encountered.</p> <p>Confirmed: Laboratory confirmation of the presence of cysticercus in tissue</p> <p>Note: Also see Taenia solium</p>	<ul style="list-style-type: none"> ▪ Diagnosis of neurocysticercosis is usually made by MRI or CT brain scans in order to identify the presence of cysticerci. If surgery is necessary, confirmation of the diagnosis can be made by demonstrating the cysticercus in the tissue involved (biopsy). ▪ X-rays can identify calcified cysticerci in tissues other than the brain. <p>Note: Blood tests are available to help diagnose an infection, but are not always accurate. Demonstration of <i>Taenia solium</i> eggs and proglottids in the feces are diagnostic of taeniasis and not cysticercosis. While suggestive, it does not necessarily prove that cysticercosis is present. Persons who are found to have eggs or proglottids in their feces should be evaluated serologically since autoinfection, resulting in cysticercosis, can occur.</p>

<p>Dengue-like illness 11704</p> <p>Dengue 10680</p> <p>Dengue, severe 11705</p>	<p>Dengue is a potentially fatal febrile illness caused by infection with any of the four dengue viruses (DENV-1, -2, -3 and -4). Dengue is transmitted primarily through the bite of <i>Aedes aegypti</i> and <i>Ae. albopictus</i> mosquitoes. For the purposes of surveillance and reporting, based on their clinical presentation, dengue cases can be categorized into three primary groups: dengue-like illness, dengue and severe dengue.</p> <p>Clinical evidence of dengue-like illness:</p> <ul style="list-style-type: none"> ▪ Fever as reported by the patient or healthcare provider <p>Clinical evidence of dengue:</p> <ul style="list-style-type: none"> ▪ Fever as reported by the patient or healthcare provider and the presence of one or more of the following signs and symptoms: <ul style="list-style-type: none"> ▪ nausea/vomiting ▪ rash ▪ aches and pains (i.e. headache, retro-orbital pain, arthralgia) ▪ tourniquet test positive ▪ leukopenia (a total white blood cell <5,000/mm³) ▪ abdominal pain ▪ persistent vomiting ▪ extravascular fluid accumulation ▪ mucosal bleeding ▪ liver enlargement >2 centimeters ▪ increasing hematocrit concurrent with rapid decrease in platelet count <p>Clinical evidence of severe dengue:</p> <ul style="list-style-type: none"> ▪ Dengue with any one or more of the following scenarios: <ul style="list-style-type: none"> ▪ severe plasma leakage evidenced by hypovolemic shock and/or extravascular fluid accumulation with respiratory distress ▪ severe bleeding from the gastrointestinal tract or vagina as defined by requirement for medical intervention including intravenous fluid resuscitation or blood transfusion ▪ severe organ involvement, including any of the following: <ul style="list-style-type: none"> ▪ elevated liver transaminases: aspartate aminotransferase (AST) or alanine aminotransferase (ALT) ≥1,000 units per liter (U/L) ▪ impaired level of consciousness and/or diagnosis of encephalitis, encephalopathy, or meningitis ▪ heart or other organ involvement including myocarditis, cholecystitis, and pancreatitis 	<ul style="list-style-type: none"> ▪ Detection of DENV nucleic acid in serum, plasma, cerebrospinal fluid (CSF), other body fluid or tissue by validated reverse transcriptase –polymerase chain reaction (PCR) , <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of DENV antigen in tissue, by IHC, <p>OR</p> <ul style="list-style-type: none"> ▪ Detection in serum or plasma of DENV NS1 antigen by a validated immunoassay, <p>OR</p> <ul style="list-style-type: none"> ▪ Cell culture isolation of DENV from serum, plasma, or CSF specimen, <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of IgM anti-DENV in serum or CSF in a traveler returning from a dengue endemic area without on-going transmission of another flavivirus, clinical evidence of co-infection with a flavivirus or recent vaccination against a flavivirus, <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of IgM anti-DENV in serum or CSF in a person living in a dengue endemic or non-endemic area of the US without evidence of other flavivirus transmission, <p>OR</p> <ul style="list-style-type: none"> ▪ IgM anti-DENV seroconversion by validated immunoassay in acute (i.e., collected <5 days of illness onset) and convalescent (i.e., collected >5 days after illness onset) serum specimens, <p>OR</p> <ul style="list-style-type: none"> ▪ IgG anti-DENV seroconversion or ≥4-fold rise in titer in serum specimens collected >2 weeks apart, and confirmed by a neutralization test (e.g., plaque reduction neutralization test) with a >4-fold higher

Ebola (HF) 11630	<p>An illness characterized by abrupt onset of fever usually accompanied by one or more of the following symptoms: severe headache, nausea, vomiting, abdominal pain, diarrhea, fatigue, weakness, myalgia, unexplained bleeding or bruising, or development of a maculopapular rash.</p> <p>Confirmed: A clinically compatible illness that is laboratory confirmed</p> <p>Suspect: A clinically compatible illness that meets one or more of the following exposures within 21-days before onset of symptoms:</p> <ul style="list-style-type: none"> ▪ Contact with blood or other body fluids of a patient with EVD, OR ▪ Residence in—or travel to—an EVD endemic area or area currently classified by CDC as experiencing an Ebola outbreak, OR ▪ Handling EVD specimens in a laboratory setting, OR ▪ Work in a laboratory that handles primates, bats, or rodents from endemic areas, OR ▪ Exposure to semen or breast-milk of an individual who had EVD within the last 9 months. 	<ul style="list-style-type: none"> ▪ RT-PCR for Ebola, OR ▪ Ebola Virus isolation in culture, OR ▪ IgM ELISA, OR ▪ Antigen-capture ELISA, OR ▪ Detection of Ebola virus antigen by Immunohistochemistry
Echinococcosis 80670	<p>Echinococcosis is an infection caused by the larval stage of tapeworms in the genus <i>Echinococcus</i>, including <i>E. granulosus</i> and <i>E. multilocularis</i>. Transmission occurs through the ingestion of tapeworm eggs in contaminated food, water, soil, dog feces, or on the contaminated coats of dogs and cats. Infection may also occur through the ingestion of cysts in the undercooked internal organs of infected intermediate hosts, such as sheep, goats and swine. Many infections are asymptomatic for years before the growing cysts cause clinical signs and symptoms associated with the affected organs. Liver involvement is associated with abdominal pain, hepatic masses, and biliary duct obstruction. Pulmonary involvement can produce chest pain, cough, and hemoptysis. Other organs, including the brain, bone and heart, may also be involved with resulting clinical signs and symptoms. Ruptured cysts may cause fever, urticaria (hives), eosinophilia and anaphylactic shock.</p> <p>Confirmed: An asymptomatic or symptomatic case that meets one or more confirmatory laboratory criteria.</p> <p>Probable: An asymptomatic or symptomatic case with <i>Echinococcus</i>-specific antibodies identified by TWO different types of serological assays.</p>	<ul style="list-style-type: none"> ▪ Detection of cysts or organ lesions using imaging techniques, including computerized tomography (CT), magnetic resonance imaging (MRI), and ultrasonography (US) AND detection of <i>Echinococcus</i>-specific antibodies, OR ▪ Detection of <i>Echinococcus spp.</i> DNA by polymerase chain reaction (PCR) in a clinical specimen, OR ▪ Histopathology or parasitology results compatible with <i>Echinococcus spp.</i> (i.e. direct visualization of the protoscolex in cyst fluid).

Fascioliasis 80663	<p>Fascioliasis (liver fluke trematode) is transmitted by eating raw watercress or other water plants contaminated with immature larvae, usually from locations around sheep, cattle, or related animals. The immature larval flukes migrate through the intestinal wall, the abdominal cavity, and the liver tissue, into the bile ducts, where they develop into mature adult flukes. In the early (acute) phase, symptoms may include fever; gastrointestinal problems such as nausea, vomiting and diarrhea; a swollen liver (hepatomegaly); liver function abnormalities, skin rashes; shortness of breath; and abdominal pain or tenderness. The chronic phase (after the parasite settles in the bile ducts), is marked by inflammation and hyperplasia and thickening of the bile ducts and gall bladder, leading to biliary lithiasis or obstruction. The symptoms of this phase such as biliary colic, nausea, intolerance to fatty food, right upper quadrant pain, epigastric pain, obstructive jaundice, and pruritus, are the result of a blockade in the biliary tract and inflammation in the gall bladder. Inflammation of the liver, gallbladder, and pancreas can also occur.</p> <p>Confirmed: A case that is laboratory confirmed</p> <p>Probable: A clinically compatible case with</p> <ul style="list-style-type: none"> ▪ Detection of <i>Fasciola</i> antibodies, or ▪ History of ingestion of watercress or freshwater plants and eosinophilia 	<ul style="list-style-type: none"> ▪ Microscopic identification of <i>Fasciola</i> eggs in feces, duodenal contents, or bile, OR ▪ Detection of <i>Fasciola</i> coproantigens (antigens found in feces) by ELISA

Hemolytic uremic syndrome, postdiarrheal (HUS) 11550	<p>Hemolytic uremic syndrome (HUS) is characterized by the acute onset of microangiopathic hemolytic anemia, renal injury, and low platelet count. Thrombotic thrombocytopenic purpura (TTP) also is characterized by these features but can include central nervous system (CNS) involvement and fever and can have a more gradual onset. Most cases of HUS (but few cases of TTP) occur after an acute gastrointestinal illness (usually diarrheal).</p> <p>Confirmed: An acute illness diagnosed as HUS or TTP that both meets the laboratory criteria and began within 3 weeks after onset of an episode of acute or bloody diarrhea</p> <p>Probable:</p> <ul style="list-style-type: none"> ▪ An acute illness diagnosed as HUS or TTP that meets the laboratory criteria in a patient who does not have a clear history of acute or bloody diarrhea in preceding 3 weeks, OR ▪ An acute illness diagnosed as HUS or TTP, that a) has onset within 3 weeks after onset of an acute or bloody diarrhea and b) meets the laboratory criteria except that microangiopathic changes are not confirmed <p>Note: See Shiga toxin-producing <i>Escherichia coli</i> (STEC) Cases meeting the criteria for both conditions should be reported under each condition.</p>	<p>The following are both present at some time during the illness:</p> <ul style="list-style-type: none"> ▪ Anemia (acute onset) with microangiopathic changes (i.e., schistocytes, burr cells, or helmet cells) on peripheral blood smear, AND ▪ Renal injury (acute onset) evidenced by either hematuria, proteinuria, or elevated creatinine level (i.e., greater than or equal to 1.0 mg/dL in a child aged less than 13 years or greater than or equal to 1.5 mg/dL in a person aged greater than or equal to 13 years, or greater than or equal to 50% increase over baseline) <p>Note: A low platelet count can usually, but not always, be detected early in the illness, but it can then become normal or even high. If a platelet count obtained within 7 days after onset of the acute gastrointestinal illness is not less than 150,000/mm³, other diagnoses should be considered.</p>
Hepatitis A, acute 10110	<p>An acute illness with at least one of the following a) discrete onset of symptoms (e.g., fever, headache, malaise, anorexia, nausea, vomiting, diarrhea, and abdominal pain), b) jaundice or c) elevated serum aminotransferase levels (ALT or AST).</p> <p>Confirmed: A case that meets the clinical case definition and is laboratory confirmed, OR a case that meets the clinical case definition and occurs in a person who has an epidemiological link with a person who has laboratory-confirmed hepatitis A</p>	<ul style="list-style-type: none"> ▪ Immunoglobulin M (IgM) antibody to hepatitis A virus (anti-HAV IgM) positive

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Hepatitis B, acute 10100	<p>An acute illness with at least one of the following a) discrete onset of symptoms*(e.g., fever, headache, malaise, anorexia, nausea, vomiting, diarrhea, and abdominal pain), b) jaundice or c) elevated serum alanine aminotransferase levels (ALT) >100 IU/L.</p> <p>Confirmed: A case that meets the clinical case definition is laboratory confirmed, and is not known to have chronic hepatitis B**</p> <p>*A documented negative hepatitis B surface antigen (HBsAg) laboratory test result within 6 months prior to a positive test result (i.e., HBsAg, hepatitis B “e” antigen [HBeAg], or hepatitis B virus nucleic acid testing [HBV NAT] including genotype) does not require an acute clinical presentation to meet the surveillance case definition.</p> <p>**A person should be considered chronically infected if hepatitis B antigen tests (HBsAg, HBeAg, and/or nucleic acid tests) have been positive for 6 months or longer or if the patient has a history of chronic hepatitis B diagnosis.</p>	<ul style="list-style-type: none"> ▪ IgM antibody to hepatitis B core antigen (anti-HBc IgM) positive, <p>OR</p> <ul style="list-style-type: none"> ▪ Hepatitis B surface antigen (HBsAg) positive
Hepatitis B virus infection, perinatal 10104	<p>Perinatal hepatitis B (HBV) in the newborn can range from asymptomatic to fulminant hepatitis.</p> <p>Confirmed: HBsAg positivity in any infant aged >1 through 24 months who was born in the US or in US territories to an HBsAg-positive mother</p>	<ul style="list-style-type: none"> ▪ Hepatitis B surface antigen (HBsAg) positive

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Hepatitis C, acute 10101	<p>An acute illness with discrete onset of symptoms* consistent with acute viral hepatitis (e.g., fever, headache, malaise, anorexia, nausea, vomiting, diarrhea, and abdominal pain), and a) jaundice or b) abnormal serum alanine aminotransferase levels (ALT level >400 IU/L).</p> <p>Confirmed: A case that meets the clinical case definition, is laboratory confirmed, and is not known to have chronic hepatitis C (HCV)</p> <p>*A documented negative HCV antibody laboratory test result followed within 6 months by a positive test (as described in the laboratory criteria for diagnosis) result does not require an acute clinical presentation to meet the surveillance case definition.</p>	<ul style="list-style-type: none"> ▪ Anti-HCV screening-test-positive with a signal to cut-off ratio predictive of a true positive as determined for the particular assay defined and listed by CDC at http://www.cdc.gov/hepatitis/HCV/LabTesting.htm , OR ▪ Recombinant immunoblot assay (HCV RIBA) positive, OR ▪ Nucleic acid testing (NAT) for HCV RNA positive (including genotype); <p>AND, if done, meets the following two criteria:</p> <ul style="list-style-type: none"> ▪ IgM antibody to hepatitis A virus (IgM anti-HAV) negative, AND ▪ IgM antibody to hepatitis B core antigen (IgM anti-HBc) negative
Hepatitis E, acute 10103	<p>Typical clinical signs and symptoms of acute hepatitis E virus (HEV) are similar to those of other types of acute viral hepatitis and include abdominal pain anorexia, dark urine, fever, hepatomegaly, jaundice, malaise, nausea, and vomiting. Other less common symptoms include arthralgia, diarrhea, pruritus, and urticarial rash. The period of infectivity following acute infection has not been determined but virus excretion in stools has been demonstrated up to 14 days after illness onset. In most hepatitis E outbreaks, the highest rates of clinically evident disease have been in young to middle-age adults; lower disease rates in younger age groups can be the result of anicteric and/or subclinical HEV infection. No evidence of chronic infection has been detected in long-term follow-up of patients with hepatitis E. The case fatality rate is low except in pregnant women where it can reach 20% among those infected during the third trimester of pregnancy.</p> <p>Confirmed: A case that meets the clinical case description and is laboratory confirmed</p> <p>Probable: A case that meets the clinical case description with supportive laboratory evidence (positive IgM antibody from labs other than CDC), OR negative tests for other acute hepatitis markers and an epidemiological link to other confirmed cases or travel history to an endemic area during exposure period</p>	<ul style="list-style-type: none"> ▪ IgM anti-HEV from CDC laboratory or PCR positive from reference laboratory <p>Note: No FDA approved tests to diagnose HEV infection are available in the United States.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Hookworm (ancylostomiasis) 80760	<p>Hookworm (ancylostomiasis) is a soil-transmitted helminth. Symptoms may include cough, itchy rash, abdominal discomfort, diarrhea, blood in the stool, loss of appetite, nausea, fatigue, or pale skin. Light hookworm infections generally produce few or no clinical effects. In heavy infections, blood loss at the site of the intestinal attachment of adult worms leads to iron deficiency anemia. In rare cases, prolonged, severe anemia can result in congestive heart failure and death. Children with heavy long-term infection may have impaired growth and delayed mental development due to the loss of iron and protein.</p> <p>Confirmed: A case that is laboratory confirmed</p>	<ul style="list-style-type: none"> ▪ Microscopic identification of <i>Ancylostoma</i> or <i>Necator</i> eggs in feces, OR ▪ Microscopic identification of <i>Ancylostoma</i> or <i>Necator</i> species of larvae cultured from the feces, OR ▪ Identification of adult worms expelled after treatment
Influenza, human isolates - [outbreaks only] 11060	<p>The flu is a contagious respiratory illness caused by influenza viruses. It can cause mild to severe illness and at times can lead to death. Symptoms of flu can include fever, headache, extreme tiredness, dry cough, sore throat, runny or stuffy nose, and muscle aches. Stomach symptoms (nausea, vomiting, and diarrhea) can occur but are more common in children than adults. Complications of flu can include bacterial pneumonia, ear infections, sinus infections, dehydration, and worsening of chronic medical conditions, such as congestive heart failure, asthma, or diabetes.</p> <p>Confirmed: Case that is clinically compatible and laboratory confirmed</p> <p>Note: Influenza is not a reportable condition in Texas. See Influenza A, novel/variant infection for reporting of novel/variant strains. See Influenza-associated pediatric mortality for reporting of influenza-associated deaths in all persons aged <18 years.</p>	<ul style="list-style-type: none"> ▪ Influenza virus isolation in tissue cell culture from respiratory specimens, OR ▪ Reverse-transcriptase polymerase chain reaction (RT-PCR) testing of respiratory specimens, OR ▪ Immunofluorescent antibody staining (direct or indirect) of respiratory specimens, OR ▪ Rapid influenza diagnostic testing of respiratory specimens, OR ▪ Immunohistochemical (IHC) staining for influenza viral antigens in respiratory tract tissue from autopsy specimens, OR ▪ Four-fold rise in influenza hemagglutination inhibition (HI) antibody titer in paired acute and convalescent sera

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Influenza A, novel/variant 11062	<p>An illness compatible with influenza virus infection (fever >100 degrees Fahrenheit, with cough and/or sore throat)</p> <p>Confirmed: A case of human infection with a laboratory confirmed novel/variant influenza A virus</p> <p>Probable: A case meeting the clinical criteria and epidemiologically linked to a confirmed case, but for which no confirmatory laboratory testing for novel/variant influenza virus infection has been performed or test results are inconclusive for a novel/variant influenza A virus infection</p> <p><u>Criteria for epidemiologic linkage:</u> a) the patient has had contact with one or more persons who either have or had the disease and b) transmission of the agent by the usual modes of transmission is plausible. A case can be considered epidemiologically linked to a laboratory-confirmed case if at least one case in the chain of transmission is laboratory confirmed.</p> <p>Suspect: A case meeting the clinical criteria in which influenza A has been detected but is pending laboratory confirmation. Any case of human infection with an influenza A virus that is different from currently circulating human influenza H1 and H3 viruses is classified as a suspect case until the confirmation process is complete.</p> <p>Typically, sporadic novel/variant influenza cases will have a history of either close contact with ill animals known to transmit novel subtypes of influenza A (such as wild birds or poultry, swine or other mammals) OR travel, within 14 days, to any country where a novel influenza A virus (such as highly pathogenic avian influenza A H5N1) has been recently identified in animals or people.</p>	<p>Identification of an influenza A virus subtype or strain that is different from currently circulating human influenza H1 and H3 strains as confirmed by CDC's influenza laboratory, by public health laboratories using CDC-approved protocols for that specific strain, or by labs using FDA-authorized tests for specific strains.</p> <ul style="list-style-type: none"> ▪ Novel/variant subtypes include, but are not limited to, H2, H5, H7, and H9 subtypes. ▪ Influenza H1 and H3 subtypes originating from a non-human species or from genetic re-assortment between animal and human viruses are also novel/variant subtypes or strains. ▪ Methods available for detection of currently circulating human influenza viruses at public health laboratories (e.g., rRT-PCR) will also detect suspected novel/variant subtypes and strains. ▪ Initial confirmation that a specific influenza A virus represents a novel/variant virus will be performed by CDC's influenza laboratory. ▪ Currently, only viral isolation, RT-PCR, gene sequencing, or a 4-fold rise in strain-specific serum antibody titers are considered confirmatory for case classification purposes.

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
<p>Influenza-associated pediatric mortality 11061</p>	<p>An influenza-associated death is defined for surveillance purposes as a death resulting from a clinically compatible illness that was confirmed to be influenza by an appropriate laboratory or rapid diagnostic test. There should be no period of complete recovery between the illness and death. Influenza-associated deaths in all persons aged <18 years should be reported.</p> <p>A death should not be reported if there is no laboratory confirmation of influenza virus infection, the influenza illness is followed by full recovery to baseline health status prior to death, the death occurs in a person 18 years of age or older, or after review and consultation there is an alternative agreed upon cause of death which is unrelated to an infectious process (For example, a child with a positive influenza test whose death clearly resulted from trauma after a car accident would not qualify as a case. However, a child with a respiratory illness and a positive influenza test whose death is attributed to another infectious cause such as staphylococcal pneumonia would still qualify as a case.).</p> <p>Confirmed: A death meeting the clinical case definition that is laboratory confirmed</p>	<p>Laboratory testing for influenza virus infection can be done on pre- or post-mortem clinical specimens, and may include identification of influenza A or B virus infections by a positive result by at least one of the following:</p> <ul style="list-style-type: none"> ▪ Influenza virus isolation in tissue cell culture from respiratory specimens, <p>OR</p> <ul style="list-style-type: none"> ▪ Reverse-transcriptase polymerase chain reaction (RT-PCR) testing of respiratory specimens, <p>OR</p> <ul style="list-style-type: none"> ▪ Immunofluorescent antibody staining (direct or indirect) of respiratory specimens, <p>OR</p> <ul style="list-style-type: none"> ▪ Rapid influenza diagnostic testing of respiratory specimens, <p>OR</p> <ul style="list-style-type: none"> ▪ Immunohistochemical (IHC) staining for influenza viral antigens in respiratory tract tissue from autopsy specimens, <p>OR</p> <ul style="list-style-type: none"> ▪ Four-fold rise in influenza hemagglutination inhibition (HI) antibody titer in paired acute and convalescent sera

Lyme disease 11080	<p>A systemic, tickborne disease with protean manifestations, including dermatologic, rheumatologic, neurologic, and cardiac abnormalities. The best clinical marker for the disease is the initial skin lesion, erythema migrans (EM). For most patients, the expanding EM lesion is accompanied by other acute symptoms, particularly fatigue, fever, headache, mildly stiff neck, arthralgia, or myalgia</p> <p>Confirmed: A case with physician-diagnosed EM \geq 5cm in size with an exposure in a high-incidence state or country* OR a case of physician-diagnosed EM of any size with laboratory confirmation, OR a case with at least one late manifestation** that has laboratory confirmation</p> <p>*Texas is considered a low-incidence state for Lyme disease. Therefore, a positive/equivocal screen is required prior to running IgM/IgG Immunoblots and additional testing is required to accompany an EM.</p> <p>**For purposes of surveillance, late manifestations include any of the following when an alternate explanation is not found:</p> <ul style="list-style-type: none"> ▪ Musculoskeletal system: recurrent, brief attacks (weeks or months) of objective joint swelling in one or a few joints, sometimes followed by chronic arthritis in one or a few joints. ▪ Nervous system: any of the following, alone or in combination: lymphocytic meningitis; cranial neuritis, particularly facial palsy (can be bilateral); radiculoneuropathy; or, rarely, encephalomyelitis. Encephalomyelitis must be confirmed by demonstration of antibody production against <i>Borrelia burgdorferi</i> in the cerebrospinal fluid (CSF), evidenced by a higher titer of antibody in CSF than in serum. ▪ Cardiovascular system: acute onset of high-grade (2nd or 3rd-degree) atrioventricular conduction defects that resolve in days to weeks and are sometimes associated with myocarditis. <p>Probable: Any other case of physician-diagnosed Lyme disease that has laboratory confirmation</p> <p>Suspect: A case of EM with no known exposure and no laboratory evidence of infection, OR a case with laboratory evidence of infection, but no clinical information available</p> <p>Note: Lyme disease reports will not be considered cases if the medical provider specifically states this is <i>not</i> a case of Lyme disease, or the only symptom listed is “tick bite” or “insect bite.”</p>	<ul style="list-style-type: none"> ▪ Positive culture for <i>Borrelia burgdorferi</i>, OR ▪ IgG immunoblot seropositivity using established criteria*** with <ul style="list-style-type: none"> ▪ Positive/Equivocal EIA or IFA test, AND ▪ Specimen collected > 30 days after symptom onset, OR ▪ IgG immunoblot seropositivity using established criteria*** with an exposure in a high-incidence state or country OR ▪ IgM immunoblot seropositivity using established criteria*** with <ul style="list-style-type: none"> ▪ Positive/Equivocal EIA or IFA test, AND ▪ Specimen collected \leq30 days after symptom onset <p>Note: ***Immunoblot interpretation criteria: It was recommended that an IgM immunoblot be considered positive if 2 of the following 3 bands are present: 23 kDa or 24 kDa (OspC), 39 kDa (BmpA), and 41 kDa (Fla). It was further recommended that an IgG immunoblot be considered positive if 5 of the following 10 bands are present: 18 kDa, 21 kDa (OspC), 28 kDa, 30 kDa, 39 kDa (BmpA), 41 kDa (Fla), 45 kDa, 58 kDa (not GroEL), 66 kDa, and 93 kDa. http://www.cdc.gov/mmwr/preview/mmwrhtml/00038469.htm (Updated 1995)</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Malaria 10130	<p>Initial symptoms of malaria are non-specific and include fever, chills, sweats, headaches, muscle pains, nausea and vomiting. In severe cases of malaria (caused by <i>P. falciparum</i>), clinical findings can also include confusion, coma, neurologic focal signs, severe anemia, and respiratory difficulties.</p> <p>Confirmed: A case that is laboratory confirmed in any person (symptomatic or asymptomatic) <u>diagnosed in the United States</u>, regardless of whether the person experienced previous episodes of malaria while outside the country</p> <p>Suspect: Detection of <i>Plasmodium</i> species by rapid diagnostic antigen testing (RDT) without confirmation by microscopy or nucleic acid testing in any person <u>diagnosed in the United States</u>, (symptomatic or asymptomatic), regardless of whether the person experienced previous episodes of malaria while outside the country</p> <p>Note: A subsequent attack experienced by the same person but caused by a different <i>Plasmodium</i> species is counted as an additional case. A subsequent attack experienced by the same person and caused by the same species in the U.S. may indicate a relapsing infection or treatment failure caused by drug resistance.</p>	<ul style="list-style-type: none"> ▪ Detection and specific identification of malaria parasite species by microscopy on blood films in a laboratory with appropriate expertise <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of <i>Plasmodium</i> species by nucleic acid test* <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of unspiciated malaria parasite by microscopy on blood films in a laboratory with appropriate expertise <p>* Laboratory-developed malaria PCR tests must fulfill CLIA requirements, including validation studies.</p>
Measles (Rubeola) 10140	<p>An illness characterized by all of the following: a generalized maculopapular rash lasting at least 3 days; a temperature $\geq 101.0^{\circ}\text{F}$ ($>38.3^{\circ}\text{C}$); and cough, coryza, or conjunctivitis.</p> <p>Confirmed:</p> <p>An acute febrile rash illness (temperature can be lower than 101° and rash < 3 days) that is:</p> <ul style="list-style-type: none"> ▪ Laboratory confirmed, OR ▪ Epidemiologically linked to a laboratory confirmed measles case 	<ul style="list-style-type: none"> ▪ IgG seroconversion or a significant rise in measles immunoglobulin G antibody level by any standard serologic assay *, <p>OR</p> <ul style="list-style-type: none"> ▪ Isolation of measles virus from a clinical specimen*, <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of measles-virus-specific nucleic acid by PCR *, <p>OR</p> <ul style="list-style-type: none"> ▪ A positive serological test for measles immunoglobulin M antibody* not otherwise ruled out by other confirmatory testing or more specific measles testing in a public health laboratory <p>*Not explained by MMR vaccination during the previous 6-45 days</p>

<p>Norovirus - [outbreaks only] 10996</p>	<p>Norovirus infection usually presents as acute-onset vomiting, watery non-bloody diarrhea with abdominal cramps, and nausea. Low-grade fever also occasionally occurs, and vomiting is more common in children. Dehydration is the most common complication, especially among the young and elderly, and can require medical attention. Symptoms usually last 24 to 60 hours. Recovery is usually complete and there is no evidence of any serious long-term sequelae. Studies with volunteers given stool filtrates have shown that asymptomatic infection can occur in as many as 30% of infections, although the role of asymptomatic infection in norovirus transmission is not well understood.</p> <p><i>Confirmed:</i> A clinically compatible case that is laboratory confirmed</p> <p><i>Probable:</i> Norovirus can be established as the probable cause of an outbreak if:</p> <ul style="list-style-type: none"> ▪ The mean (or median) illness duration is 12 to 60 hours, AND ▪ The mean (or median) incubation period is 24 to 48 hours, AND ▪ More than 50% of people have vomiting, AND ▪ No bacterial agent is found 	<ul style="list-style-type: none"> ▪ Polymerase chain reaction (PCR) can be used to test stool and emesis samples, as well as environmental swabs in special studies. (Identification of norovirus can best be made from stool specimens taken within 48 to 72 hours after onset of symptoms. Virus can sometimes be found in stool samples taken as late as 2 weeks after recovery.) <p>OR</p> <ul style="list-style-type: none"> ▪ Detection of norovirus by direct and immune electron microscopy of fecal specimens, <p>OR</p> <ul style="list-style-type: none"> ▪ Fourfold increase of norovirus antibodies in acute- and convalescent-phase blood samples <p>Note: The etiology of GI outbreaks should be confirmed by submitting specimens to the DSHS Laboratory. Sequencing of norovirus strains found in clinical and environmental samples has greatly helped in conducting epidemiologic investigations.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
<p>Novel coronavirus causing severe acute respiratory disease 10575</p>	<p>Severe acute respiratory syndrome (SARS) is a viral respiratory illness caused by a novel coronavirus. SARS was first identified in 2003 with the SARS-associated coronavirus (SARS-CoV). SARS-CoV has not been detected since the 2003 outbreak ended. However, in 2012 a new coronavirus causing an acute severe respiratory disease was detected in countries in or near the Arabian Peninsula--Middle East Respiratory Syndrome coronavirus (MERS-CoV). Symptoms of a novel coronavirus causing an acute respiratory syndrome may include fever and cough in addition to pneumonia or acute respiratory distress syndrome (ARDS).</p> <p>Clinical criteria for the specific novel coronavirus will be determined by the Centers for Disease Control and Prevention (CDC). Case definitions for confirmed, probable and suspect cases may be redefined based on the specific novel coronavirus. Additionally, CDC may require that patients undergo testing for alternate causes of infection including all clinically indicated tests for community acquired pneumonia, before being considered a probable or suspect case.</p> <p>Confirmed: A person who has laboratory confirmation of infection with a novel coronavirus</p> <p>Probable: A person who meets the criteria for a suspect case, has absent or inconclusive* laboratory results for novel coronavirus infection, and is a close contact** of a laboratory confirmed case</p> <p>Suspect: A person who meets the clinical criteria AND at least one of the following:</p> <ol style="list-style-type: none"> 1) Has recent travel history to any country where a novel coronavirus has been recently identified in people 2) Has had close contact** with a symptomatic person who recently traveled to any country where a novel coronavirus has been recently identified in people 3) Is a member of a cluster of patients with severe acute respiratory illness (e.g., fever and pneumonia requiring hospitalization) of unknown etiology in which a novel coronavirus is being evaluated, in consultation with state and local health departments 4) Has a recent history of other relevant exposures, as defined by CDC <p>*Examples of laboratory results that may be considered inconclusive include a positive test on a single PCR target, a positive test with an assay that has limited performance data available, or a negative test on an inadequate specimen.</p> <p>**Close contact definition can be found on the CDC MERS website: http://www.cdc.gov/coronavirus/mers/case-def.html</p>	<ul style="list-style-type: none"> ▪ Identification of a novel coronavirus that is different from currently circulating human coronaviruses as confirmed by CDC's laboratory, by public health laboratories using CDC-approved protocols for a specific novel strain, or by labs using an FDA-approved test for a specific novel strain ▪ Initial confirmation that a specific coronavirus represents a novel virus will be determined by the CDC ▪ Other laboratory confirmation criteria may be defined by CDC for the specific novel coronavirus

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
<p>Prion diseases such as Creutzfeldt-Jakob disease (CJD) 80060 (continued on next page)</p>	<p>Creutzfeldt-Jakob disease (CJD) is a human prion disease described as rapidly progressive, invariably fatal, and neurodegenerative. Human prion diseases include sporadic forms of disease (sporadic CJD, sporadic Fatal Insomnia, Variably Protease-Sensitive Prionopathy), genetic or familial forms of disease (familial CJD, Familial Fatal Insomnia, and Gerstmann-Sträussler-Scheinker disease) and acquired forms of disease (iatrogenic CJD and variant CJD). Classical sporadic CJD presentation consists of rapidly progressive dementia, visual abnormalities, myoclonus, or cerebellar dysfunction (where both balance abnormalities and muscle incoordination are seen which commonly present as gait, speech, and swallowing disorders). Most patients eventually develop pyramidal and extrapyramidal dysfunction such as abnormal reflexes (hyperreflexia), spasticity, tremors, and rigidity. Akinetic mutism appears late in the disease. Median duration of illness is 4 months; the duration of illness rarely exceeds 12 months.</p> <p>For purposes of surveillance, CJD notification also includes Kuru, Gerstmann-Sträussler-Scheinker (GSS) disease, fatal familial insomnia (FFI), sporadic fatal insomnia (sFI), Variably Protease-Sensitive Prionopathy (VPSPr) and any novel prion disease affecting humans.</p> <p>Sporadic CJD (sCJD): Confirmed: Satisfactory confirmatory test finding on autopsy or biopsy tissue Probable: Rapidly progressive dementia AND at least two of the following clinical features:</p> <ul style="list-style-type: none"> a) Myoclonus b) Visual Or Cerebellar Signs c) Pyramidal/Extrapyramidal Signs d) Akinetic Mutism <p>AND satisfying at least 1 of the supportive laboratory criteria, AND absence of routine investigations indicating an alternative diagnosis</p> <p>Possible: Progressive dementia AND at least two of the following clinical features:</p> <ul style="list-style-type: none"> a) Myoclonus b) Visual Or Cerebellar Signs c) Pyramidal / Extrapyramidal Signs d) Akinetic mutism <p>WITH a duration of illness < 2 years, AND the absence of supportive laboratories, AND the absence of routine investigations indicating an alternative diagnosis</p>	<p>Confirmatory Laboratory Criteria - sporadic, genetic, & iatrogenic CJD Diagnosis by standard neuropathological techniques AND/OR Immunohistochemistry AND/OR Western blot AND/OR Presence of scrapie-associated fibrils from biopsy or autopsy obtained brain tissue</p> <p>Supportive Laboratory Criteria - sporadic, genetic, & iatrogenic CJD</p> <ul style="list-style-type: none"> ▪ CSF 14-3-3 protein: ELISA reported as elevated or above normal limits or Western blot reported positive. If 14-3-3 protein is the only supportive test used in determining classification, then duration of illness must be < 2 years. ▪ RT-QuIC: Positive ▪ Tau protein: Positive ▪ EEG: Reported as “typical of” or “consistent with” sporadic CJD or the report indicates the presence of generalized bi- or triphasic “periodic sharp wave complexes” (PSWC) at a frequency of 1-2 per second. No limit on duration of illness. ▪ MRI: High signal abnormalities in the caudate nucleus and/or putamen on diffusion-weighted imaging (DWI) or fluid attenuated inversion recovery (FLAIR). No limitation on duration of illness. <p>(Continued on next page– see Exclusion Criteria.)</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
<p>Prion diseases such as Creutzfeldt-Jakob disease (CJD)</p> <p>(continued on next page)</p>	<p>Iatrogenic CJD (iCJD): <i>Confirmed:</i> Progressive cerebellar syndrome in a recipient of human cadaveric-derived pituitary hormone OR meets sCJD criteria WITH a recognized exposure risk (e.g., dura matter grafts)</p> <p>Familial CJD (fCJD): A classification of <i>confirmed</i> or <i>probable</i> requires that the criteria for sCJD are met plus the presence of a confirmed or probable CJD classification in a first degree relative AND/OR a neuropsychiatric disorder plus fCJD-specific PRNP gene mutation are present.</p> <p>Familial Fatal Insomnia (FFI): Meets the fCJD classification criteria AND pathology demonstrates thalamic atrophy AND/OR presence of a FFI-specific PRNP gene mutation</p> <p>Sporadic Fatal Insomnia (sFI): Classification follows FFI criteria but is not epi-linked (no 1st degree relatives with evidence of disease). On pathology the glycosylation pattern is similar to sCJD rather than to FFI.</p> <p>Gerstmann-Sträussler-Scheinker disease (GSS): A family with dominantly inherited progressive ataxia and/or dementia and one of a variety of PRNP mutations. Confirmatory Laboratory Criteria: Encephalo(myelo)pathy with multi-centric PrP plaques AND thalamic degeneration WITH a background of variable spongiform change in cerebrum</p> <p>Kuru: Spongiform encephalopathy epidemiologically linked to the Fore population of Papua New- Guinea</p>	<p>Exclusion Criterion: On neurohistopathological analysis of whole brain autopsy tissue, the absence of findings consistent with prion disease (negative results) is sufficient to “rule out” possible and probable cases and reclassify as “Not a Case”.</p> <p>Notes: Whole brain autopsy and neuropathology is the only way to confirm or rule-out prion disease. Biopsy tissue can only confirm presence of prion disease but is not sufficient to rule-out prion disease. Autopsy or postmortem biopsy (when autopsy is not possible) is strongly encouraged, while biopsy on living patients should be reserved for diagnosing treatable diseases. The National Prion Disease Pathology Surveillance Center (NPDPSC) performs analysis on CSF, blood, and brain tissue. They provide free transport, shipping, and autopsy services for suspected cases of CJD (the family must initiate contact). Physicians are strongly encouraged to confirm the diagnosis of CJD by discussing & arranging autopsy with the NPDPSC and family members. Autopsy is “highly suggested” for all cases with onset age under 55 years or physician diagnosed CJD.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Prion diseases such as Creutzfeldt-Jakob disease (CJD)	<p>Variant CJD (vCJD) is characterized by epidemiologic exposure to the causative agent of bovine spongiform encephalopathy (BSE) through consumption of contaminated meat, a prolonged incubation period of ~ 8 years (possibly decades), and presence of a neuropsychiatric disease that is progressive and invariably fatal. Median age at onset of symptoms is 28 years. Clinical presentation: early psychiatric symptoms (anxiety/depression), paraesthesia, delayed development of neurologic signs (> 4 months), and duration of illness lasting over 6 months.</p> <p>Confirmed: Confirmatory laboratory criteria are met</p> <p>Suspect*: The following criteria are met:</p> <ul style="list-style-type: none"> a) Current age or age at death <55 years (a brain autopsy is recommended, however, for all physician-diagnosed CJD cases) b) Psychiatric symptoms at illness onset AND/OR persistent painful sensory symptoms (frank pain and/or dysesthesia) c) Dementia AND development >4 months after illness onset of at least two of the following five neurologic signs: poor coordination, myoclonus, chorea, hyperreflexia, or visual signs. (If persistent painful sensory symptoms exist, >4 months delay in the development of the neurologic signs is not required.) d) A normal or an abnormal EEG, BUT NOT the diagnostic EEG changes often seen in classic CJD e) Duration of illness of over 6 months f) Routine investigations of the patient do not suggest an alternative, non-CJD diagnosis g) No history of receipt of cadaveric human pituitary growth hormone or a dura mater graft h) No history of CJD in a first degree relative or PRNP gene mutation in the patient <p>OR</p> <ul style="list-style-type: none"> ▪ Presence of “bilateral pulvinar high signal” or “pulvinar sign” or “symmetrical, bilateral high signal in the posterior thalamic nuclei” on MRI, AND ▪ Presence of all of the following: a progressive neuropsychiatric disorder, d, e, f, & g of the above criteria AND four of the following five criteria: <ul style="list-style-type: none"> ▪ Early psychiatric symptoms (anxiety, apathy, delusions, depression, withdrawal) ▪ Persistent painful sensory symptoms (frank pain and/or dysesthesia, and/or paraesthesia) ▪ Ataxia ▪ Myoclonus or chorea or dystonia ▪ Dementia <p>*A history of possible exposure to bovine spongiform encephalopathy (BSE) such as residence or travel to a BSE-affected country after 1980 increases the index of suspicion for a variant CJD diagnosis.</p>	<p>Confirmatory Laboratory Criteria – vCJD (brain tissue)</p> <ul style="list-style-type: none"> ▪ Numerous widespread kuru-type amyloid plaques surrounded by vacuoles in both the cerebellum and cerebrum (i.e., florid plaques) AND ▪ Spongiform change and extensive prion protein deposition shown by immunohistochemistry throughout the cerebellum and cerebrum <p>Supportive Laboratory Criteria - vCJD</p> <ul style="list-style-type: none"> ▪ EEG with normal or abnormal findings BUT WITHOUT findings consistent with sporadic CJD (absence of “periodic sharp wave complexes” - PSWC), OR EEG not reported or performed ▪ Presence of “bilateral pulvinar high signal” OR “pulvinar sign” OR “symmetrical, bilateral high signal in the posterior thalamic nuclei” on MRI (relative to other deep gray-matter nuclei) <p>Notes: Whole brain autopsy and neuropathology is the only way to confirm or rule-out prion disease. Biopsy tissue can only confirm presence of prion disease but is not sufficient to rule-out prion disease. Autopsy or postmortem biopsy (when autopsy is not possible) is strongly encouraged, while biopsy on living patients should be reserved for diagnosing treatable diseases. The National Prion Disease Pathology Surveillance Center (NPDPS) performs analysis on CSF, blood, and brain tissue. They provide free transport, shipping, and autopsy services for suspected cases of CJD (the family must initiate contact). Physicians are strongly encouraged to confirm the diagnosis of CJD by discussing & arranging autopsy with the NPDPS and family members. Autopsy is “highly suggested” for all cases with onset age under 55 years or physician diagnosed CJD.</p>

Q Fever, acute 10257	<p>Q fever is a zoonotic disease caused by the rickettsia <i>Coxiella burnetii</i>. Asymptomatic infection occurs in approximately half of those infected. Exposure to Q fever is usually via aerosol and the source can be unknown (especially for chronic infection). Exposure can be associated with goats, sheep, or other livestock, but direct contact with animals is not required, and variable incubation periods can be dose dependent. Acute infection, if symptomatic, is characterized by acute onset of fever accompanied by rigors, myalgia, malaise, and severe retrobulbar headache and can include symptoms such as fatigue, night sweats, dyspnea, confusion, nausea, diarrhea, abdominal pain, vomiting, non-productive cough, or chest pain. Acute hepatitis, atypical pneumonia, and meningoencephalitis may be present with severe disease. Pregnant women are at risk for fetal death and abortion. Clinical laboratory findings can include elevated liver enzyme levels, leukocytosis, and thrombocytopenia.</p> <p>Confirmed: A clinically compatible case that is laboratory confirmed</p> <p>Probable: A clinically compatible case with a single supportive IgG-specific antibody titer to <i>C. burnetii</i> Phase II antigen of $\geq 1:128$ by IFA, OR serological evidence of elevated IgG or IgM antibody titer to <i>C. burnetii</i> by ELISA, dot-ELISA, or LA</p>	<ul style="list-style-type: none"> ▪ Serological evidence of a four-fold change in IgG-specific antibody titer to <i>C. burnetii</i> Phase II antigen by IFA between paired serum samples (one taken during the first week of illness and a second 3-6 weeks later), OR ▪ Detection of <i>C. burnetii</i> DNA in a clinical specimen by polymerase chain reaction (PCR) assay, OR ▪ Demonstration of <i>C. burnetii</i> antigen in a clinical specimen by immunohistochemical (IHC) methods, OR ▪ Isolation of <i>C. burnetii</i> from a clinical specimen in cell culture
Q Fever, chronic 10258	<p>Chronic Q fever is characterized by a <i>Coxiella burnetii</i> infection that persists for more than 6 months. Potentially fatal endocarditis can evolve months to years after acute infection, particularly in persons with underlying valvular disease. Infections of aneurysms and vascular prostheses have been reported. Immunocompromised individuals are particularly susceptible. Rare cases of chronic hepatitis without endocarditis, osteomyelitis, osteoarthritis, and pneumonitis have been described.</p> <p>Clinical evidence: Chronic hepatitis, osteomyelitis, osteoarthritis, or pneumonitis (in the absence of other known etiology); suspected infection of a vascular aneurysm or vascular prosthesis; or newly recognized, culture-negative endocarditis (particularly in a patient with previous valvulopathy or compromised immune system).</p> <p>Confirmed: A clinically compatible (meets clinical evidence criteria) case of chronic illness that is laboratory confirmed</p> <p>Probable: A clinically compatible case of chronic illness with an antibody titer to <i>C. burnetii</i> Phase I IgG antigen that is $\geq 1:128$ and $< 1:800$ by IFA</p>	<ul style="list-style-type: none"> ▪ Serological evidence of IgG antibody to <i>C. burnetii</i> Phase I antigen of $\geq 1:800$ by IFA OR ▪ Detection of <i>C. burnetii</i> DNA in a clinical specimen by polymerase chain reaction (PCR) assay, OR ▪ Demonstration of <i>C. burnetii</i> antigen in a clinical specimen by immunohistochemical (IHC) methods, OR ▪ Isolation of <i>C. burnetii</i> from a clinical specimen in cell culture

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
Rabies, animal 10340	<p>All warm-blooded animals, including humans, are susceptible to rabies. In Texas, skunks, bats, coyotes, and foxes are the most commonly infected animals. Domestic dogs, cats, and livestock usually acquire rabies infections from wild animals.</p> <p>Medical authorities distinguish between "furious" and "dumb" rabies on the basis of clinical signs. In the furious variety, the "mad dog" symptoms are pronounced. The animal is irritable and will snap and bite at real or imaginary objects. It can run for miles and attack anything in its path. The animal is extremely vicious and violent. Paralysis sets in shortly, usually affecting the hind legs first. Death follows four to seven days after the onset of clinical signs. In dumb rabies, the prominent symptoms are drowsiness and paralysis of the lower jaw. The animal can appear to have a bone lodged in its throat, sometimes causing owners to force open an animal's mouth to investigate and become unwittingly exposed to rabies. Animals with dumb rabies have no tendency to roam but will snap at movement. They are completely insensitive to pain, and usually become comatose and die from three to ten days after first symptoms appear.</p> <p>Confirmed: A case that is laboratory confirmed</p>	<ul style="list-style-type: none"> ▪ A positive direct fluorescent rabies antibody test (preferably performed on central nervous system tissue), <p>OR</p> <ul style="list-style-type: none"> ▪ Isolation of rabies virus (in cell culture or in a laboratory animal)

<p>Smallpox 11800</p>	<p>An illness with acute onset of fever $\geq 101^{\circ}\text{F}$ ($\geq 38.3^{\circ}\text{C}$) followed by a rash characterized by firm, deep seated vesicles or pustules in the same stage of development without other apparent cause.</p> <p>Confirmed: A case of smallpox that is laboratory confirmed, or a case that meets the clinical case definition and is epidemiologically linked to a laboratory confirmed case</p> <p>Probable: A case that meets the clinical case definition without laboratory confirmation or epidemiological link to a confirmed case, OR a case with an atypical presentation of smallpox (e.g., hemorrhagic type, flat type, and variola sine eruptione) that has an epidemiological link to a confirmed case of smallpox</p> <p>For full descriptions of atypical smallpox presentations see Guide A: Smallpox Surveillance and Case Reporting; Contact Identification, Tracing, Vaccination, and Surveillance; and Epidemiologic Investigation.</p> <p>Suspect: A case with a generalized, acute vesicular or pustular rash illness with fever preceding development of rash by 1-4 days</p> <p>Exclusion Criteria: A case can be excluded as a suspect or probable smallpox case if an alternative diagnosis fully explains the illness or appropriate clinical specimens are negative for laboratory criteria for smallpox.</p> <p>Note: The smallpox case definition above is to be used only during post-event surveillance. For pre-event surveillance purposes, where the likelihood of smallpox occurring is considered to be extremely low, the suggested approach to surveillance relies on a highly specific clinical case definition, which is focused on identifying a classic case (ordinary type) of smallpox. In the absence of known smallpox disease, the predictive value of a positive smallpox diagnostic test is extremely low, close to zero; therefore, testing to rule out smallpox should be limited to cases that fit the clinical case definition in order to lower the risk of obtaining a false positive test result.</p> <p>The case definition described in Guide A of the Smallpox Response Plan and Guidelines (Version 3) on the CDC bioterrorism preparedness website (URL: http://www.bt.cdc.gov/agent/smallpox/response-plan/index.asp) includes different criteria for a suspect case than the smallpox case definition the Council of State and Territorial Epidemiologists approved for use in the National Notifiable Diseases Surveillance System (NNDSS). The smallpox case definition on the CDC bioterrorism web site is more sensitive and less specific than the case definition for the NNDSS, in that a "Suspect" case is defined as: "a case with febrile rash illness with fever preceding the development of rash by 1-4 days." http://www.bt.cdc.gov/agent/smallpox/diagnosis/casedefinition.asp</p>	<ul style="list-style-type: none"> ▪ Polymerase chain reaction (PCR) identification of variola DNA in a clinical specimen, <p>OR</p> <ul style="list-style-type: none"> ▪ Isolation of smallpox (variola) virus from a clinical specimen (Level D laboratory only; confirmed by variola PCR) <p>Note: Laboratory diagnostic testing for variola virus should be conducted in a CDC Laboratory Response Network (LRN) laboratory utilizing LRN-approved PCR tests and protocols for variola virus. Initial confirmation of a smallpox outbreak requires additional testing at CDC.</p> <p>Generic orthopox PCR and negative stain electron microscopy (EM) identification of a pox virus in a clinical specimen are suggestive of an orthopox virus infection but not diagnostic for smallpox.</p>

Condition/Code	Case Definition/Case Classification	Laboratory Confirmation Tests
<p>Spotted fever group rickettsioses 10250</p>	<p>Spotted fever group rickettsioses (SFGR) are a group of tick-borne infections caused by some members of the genus <i>Rickettsia</i>. The most well-known SFGR is Rocky Mountain spotted fever (RMSF), an illness caused by <i>Rickettsia rickettsii</i>. Disease onset for RMSF averages one week following a tick bite. Illness is characterized by acute onset of fever and can be accompanied by headache, malaise, myalgia, nausea/vomiting, or neurologic signs; a macular or maculopapular rash may appear 4-7 days following onset in many (~80%) patients, often present on the palms and soles. RMSF can be fatal in as many as 20% of untreated cases, and severe fulminant disease can occur. In addition to RMSF, human illness associated with other spotted fever group <i>Rickettsia</i> species, including infection with <i>Rickettsia parkeri</i>, has also been reported. In these patients, clinical presentation appears similar to, but can be milder than, RMSF; the presence of an eschar at the site of tick attachment has been reported for some other SFGR.</p> <p><i>Clinical evidence:</i> Any reported acute onset of fever and one or more of the following: rash, eschar, headache, myalgia, anemia, thrombocytopenia, or any hepatic transaminase elevation.</p> <p>Confirmed: Clinically compatible case (meets clinical evidence criteria) that is laboratory confirmed</p> <p>Probable: Clinically compatible case (meets clinical evidence criteria) with serological evidence of elevated IgG or IgM antibody reactive with <i>R. rickettsii</i> or other spotted fever group antigen* by IFA (serologic titer of $\geq 1:128$),</p> <p>Note: Because serologies for rickettsial diseases can be cross-reactive, specimens should be tested against a *panel of <i>Rickettsia</i> antigens, including, at a minimum, <i>R. rickettsia</i> and <i>R. typhi</i>, to differentiate between SFG and non-SFG <i>Rickettsia</i> spp. In addition, according to CDC, Rickettsial IgM tests lack specificity (resulting in false positives); thus, IgG titers are considered to be much more reliable.</p> <p>* <i>Specimens can be forwarded to the DSHS Serology lab for Rickettsial panel testing.</i></p> <p>See Rickettsia Classification</p>	<ul style="list-style-type: none"> ▪ Serological evidence of an elevation (four-fold change) in immunoglobulin G (IgG)-specific antibody titer reactive with <i>Rickettsia rickettsii</i> or other spotted fever group antigen* between paired serum specimens (one taken in the first week of illness and a second 2-4 weeks later), as measured by a standardized indirect immunofluorescence assay (IFA), OR ▪ Detection of <i>R. rickettsii</i> or other spotted fever group DNA* in a clinical specimen by polymerase chain reaction (PCR) assay, OR ▪ Demonstration of spotted fever group antigen* in a biopsy/autopsy specimen by IHC, OR ▪ Isolation of <i>R. rickettsii</i> or other spotted fever group rickettsia* from a clinical specimen in cell culture <p>* Note: Spotted fever group species included are: <i>R. aeschlimannii</i>, <i>R. africae</i>, <i>R. australis</i>, <i>R. conorii</i>, <i>R. heilongjiangensis</i>, <i>R. helvetica</i>, <i>R. honei</i>, <i>R. japonica</i>, <i>R. marmionii</i>, <i>R. massiliae</i>, <i>R. parkeri</i>, <i>R. rickettsii</i>, <i>R. sibirica</i>, <i>R. sibirica mongolotimonae</i>, <i>R. slovaca</i>. Trichuriasis 80790	<p>Trichuriasis is a soil-transmitted helminth. People with light infections usually have no symptoms or only peripheral blood eosinophilia. People with heavy symptoms can experience frequent, painful passage of stool that contains a mixture of mucus, water, and blood. Rectal prolapse can also occur. Children with heavy infections can become severely anemic and growth-retarded.</p> <p>Confirmed: A case that is laboratory confirmed</p>	<ul style="list-style-type: none"> ▪ Microscopic identification of <i>Trichuria</i> eggs or worms in feces, <p>OR</p> <ul style="list-style-type: none"> ▪ Observation during sigmoidoscopy, proctoscopy, or colonoscopy of <i>Trichuria</i> worms characterized by a threadlike form with an attenuated, whip-like end, <p>OR</p> <ul style="list-style-type: none"> ▪ Identification of worms on prolapsed rectal mucosa

<p>Tuberculosis 10220</p>	<p>Tuberculosis (TB) is a chronic bacterial infection caused by <i>Mycobacterium tuberculosis</i>, usually characterized pathologically by the formation of granulomas. The most common site of infection is the lung, but other organs may be involved.</p> <p>For purposes of surveillance, a case of TB is defined on the basis of laboratory or clinical evidence of active disease due to <i>M. tuberculosis</i> complex.*</p> <p>Note: All isolates reported as <i>M. tuberculosis</i> complex should be further evaluated to determine if they are <i>M. bovis</i> or <i>M. bovis</i> (BCG).</p> <p>Confirmed: a case that meets the clinical case definition or is laboratory confirmed</p> <p>Verified: a case that is verified by an authorized TB surveillance designee, on the basis of laboratory or clinical evidence of active disease due to <i>M. tuberculosis</i> complex and meets the criteria for a Texas resident</p> <p>Counted: a case that is confirmed, verified and reported to the CDC for inclusion in statistics for annual incidence in Texas and national morbidity reports</p> <p>Multidrug-resistant TB (MDR): resistant to at least isoniazid and rifampin; MDR TB is more difficult to treat than drug-susceptible TB</p> <p>Extensively drug resistant TB (XDR): the occurrence of TB whose <i>M. tuberculosis</i> isolates are resistant to isoniazid and rifampin, plus resistant to any fluoroquinolone and at least one of three injectable second-line drugs (i.e., amikacin, kanamycin, or capreomycin)</p> <p>Recurrence: A patient who has</p> <ul style="list-style-type: none"> ▪ a negative culture result while receiving anti-TB therapy, but at some point after therapy is completed, either the culture result becomes positive for <i>M. tuberculosis</i> or the patient has clinical or radiologic deterioration that is consistent with TB disease, OR ▪ a negative smear and culture result (e.g., clinical case) at diagnosis and while receiving anti-TB therapy, but at some point after therapy is completed, either the patient has a culture result that is positive for <i>M. tuberculosis</i> or has clinical or radiologic deterioration that is consistent with TB disease. <p>Note: A case should not be counted twice within any consecutive 12-month period. However, a case occurring in a patient who had previously had verified TB disease should be reported and counted again if more than 12 months have elapsed since the patient completed therapy. A case should also be reported and counted again if the patient was lost to supervision for greater than 12 months and TB disease can be verified again.</p>	<ul style="list-style-type: none"> • Isolation of <i>M. tuberculosis</i> complex from a clinical specimen, OR • Demonstration of <i>M. tuberculosis</i> complex from a clinical specimen by nucleic acid amplification test, OR • Demonstration of acid-fast bacilli in a clinical specimen when a culture has not been or cannot be obtained. <p>Note: Mycobacterial diseases other than those caused by <i>M. tuberculosis</i> complex should not be counted in tuberculosis morbidity statistics unless there is concurrent tuberculosis.</p> <p>*Because most laboratories use tests that do not routinely distinguish <i>Mycobacterium tuberculosis</i> from very closely related species, these laboratories report culture results as being positive or negative for “<i>Mycobacterium tuberculosis</i> complex.” Although in almost all cases of human disease isolates in the <i>M. tuberculosis</i> complex are, in fact, <i>M. tuberculosis</i>, other species are possible. Other species in the <i>Mycobacterium tuberculosis</i> complex include <i>M. bovis</i>, <i>M. africanum</i>, <i>M. microti</i>, <i>M. canettii</i>, <i>M. caprae</i>, and <i>M. pinnipedii</i>. Although most of these other species are newly described, their inclusion in <i>M. tuberculosis</i> complex should not impact public health laboratories or programs, because only a few laboratories identify to the species level. These species are almost identical in DNA homology studies. In terms of their ability to cause clinical disease or be transmissible from person to person, these species behave like <i>M. tuberculosis</i>; therefore, disease caused by any of the organisms should be reported as TB. The only exception is the BCG strain of <i>M. bovis</i>, which may be isolated from</p>
